

Copilot Studio Training – Day 09

Agenda:

- Variables in Copilot Studio
- Create Multilingual Copilot Agent
- Get Started with Components Collections in Copilot Studio
- Security in Copilot Studio
- Distribute Copilot Studio

What Are Variables?

Variables in Copilot Studio store and pass information during conversations. They can be used to:

- Route users through different conversation paths.
- Send input parameters to Power Automate flows or Bot Framework skills.
- Retain information across topics in a chatbot.

Types of Variables

1. By Scope:

- **Topic Variable** – Used within a specific topic.
- **Global Variable** – Accessible across all topics in the bot.
- **Environment Variable** – Defined at the environment level and used across different bots.

2. By Creation:

- **System Variables** – Auto-created when provisioning a copilot, providing context like user details and bot metadata.
- **Custom Variables** – Manually created for specific use cases.

3. Special Variable Categories:

- **Activity Variables** – Store details about user actions (e.g., channel ID, attachments).
- **Bot Variables** – Store bot-related information (e.g., bot ID, environment ID).
- **Conversation Variables** – Store data related to user interactions (e.g., conversation ID, local time zone).
- **User Variables** – Store logged-in user details (e.g., email, name, language).

Variable Data Types

- **Boolean**

- **Number**
- **Float**
- **String**
- **Date/Time**
- **Table**
- **Record**
- **Choice**

Creating and Managing Variables

1. Creating a Variable:

- Navigate to a topic.
- Click on the node where the variable is needed.
- Use **Variable Management** to create a new variable.
- Assign a value using formula expressions (e.g., `date(2024, 08, 02)`).

2. Defining Variable Scope:

- Enable "**Receive values from other topics**" for cross-topic access.
- Enable "**Return values to original topic**" for sending data back.

3. Using Global Variables:

- Define a variable as **Global** to make it accessible across multiple topics.
- Ensure **external sources can set values** for broader integrations.

Allow to carry between sessions

- Persists the variable value across user sessions.
- If checked, the value is saved and reused when the user comes back later.
- If unchecked, the value resets when the session ends.

External sources can set value

- Allows **Power Automate flows, APIs, or external integrations** to update this variable.
- Useful when calling actions or flows that return values.

External sources can receive value

- Allows the variable to be **passed to external systems** (like Power Automate).
- Useful when sending user input to a flow.

Demo Recap

- Created multiple variables of different types (string, date, table, time).
- Configured topic-specific and global variables.
- Demonstrated variable data type recognition.
- Showed how to pass values between topics.

Key Takeaways

- Variables help manage conversation flow and data storage in Copilot Studio.
- System variables provide built-in contextual data.
- Global variables allow seamless data sharing across topics.
- Custom variables offer flexibility for chatbot logic.

Language Translation in Microsoft Copilot Studio

Overview:

- Microsoft Copilot Studio allows creating bots with multiple languages.
- One **primary language** is required, with **multiple secondary languages** as options.
- **23+ languages** are supported as of July 2025

Steps to Configure Multi-language Support:

1. **Provision a bot** with a primary language.
2. **Add secondary languages** from the settings.
3. **Download localization files** (JSON or .resx).
4. **Manually translate** text within the file.
5. **Re-upload the updated file** to Copilot Studio.
6. **Publish & test** the bot in different languages.

Testing & Limitations:

- Secondary languages make topics **read-only** (only editable in the primary language).
- Multi-language bots must use **Classic Mode**, as **Generative AI Mode does not support multiple languages**.

CONFIDENTIAL

Use Case 01 – A Smart Agent for UAE Travel Assistance

Objective

The goal of this exercise is to understand and implement **multilingual Agent** for UAE Travel company who's offering different travel options for the visitors who want to visit their country. We need to use <https://www.visitdubai.com/> as KB to get the generative AI answers from this website. Let's build this Agent which accept the answer in English and Hindi Languages.

Solution:

Prompt to create Agent:

I want to create TravelMate, a smart virtual assistant that helps tourists plan their perfect vacation in Dubai. The assistant should respond in a friendly and engaging manner, making the travel planning experience smooth and enjoyable.

Knowledge Base: <https://www.visitdubai.com/>

Create One Topic using Generative AI:

Topic Name: Book a Trip

Description: Let someone book their travel vacation for Dubai. Let them enter their Name, Email, Phone and Places they wish to visit along with how many nights of holiday they're planning? Upon successful submission, create Travel request in the system.

Exercise:

1. Based on the Topic, it should make Generative AI Query to create personalized vacation.
 - Use Generative AI node and Power Fx
2. Convert this Agent to Multilingual. So, it can work for multiple Languages.

Component Collections in Microsoft Copilot Studio

Overview:

- **Component Collection** is a **feature** that allows **reusable components** across multiple copilots.
- Helps in sharing **topics, actions, entities, and knowledge** across bots within the same **tenant**.

User Permissions:

- You must be the person who created the collection or have the **system customizer** or **system admin role** to edit or add a component collection to an agent.
- Other agent authors can see and use the collection but cannot change the components inside.

Key Features:

- **Reuse topics** created in one copilot across others.
- **Admin-only editing:** System admin/customizer roles can modify collections; all copilot authors can consume them.
- **Export & import solutions** to migrate collections across environments.

Ways to Create a Component Collection:

1. **From Copilot Settings** → Navigate to **Component Collection**.
2. **From the Library Page** → Add a **new component collection**.

Steps to Share Components Across Copilots:

1. **Create a component collection** in the copilot settings.
2. **Add topics, actions, entities, or knowledge** to the collection.
3. **Use solutions** in PowerApps (make.powerapps.com) to manage them.
4. **Attach the component collection** to other copilots (agents).
5. **Updates to source topics** will reflect in all copilots using that component.

Use Case 02: Understand Component Collection and Practically Implement

Objective:

From Use Case 01, we created TravelMate Agent. Make sure, we create one reusable Topic Collection which we can consume to multiple Agents. Also try to add Knowledge Source and action if possible.

Sharing Copilots in Microsoft Copilot Studio

Overview:

- Copilots can be shared with **users, security groups, or via email**.
- Permissions and **security roles** define what users can do.

Security Roles in Copilot Studio:

1. **Bot Author** – Can **create and edit** copilots.
2. **Bot Contributor** – Can **update** existing copilots.
3. **Bot Transcript Viewer** – Can **view conversation transcripts** stored in Dataverse.

Additional Permissions:

- **Manager Role:** Allows sharing, editing, and configuring copilots.
- **Power Automate User:** Required if the copilot interacts with **Power Automate flows**.
- **Dataverse Environment Maker:** Needed to create components in the **Power Platform environment**.

How to Share a Copilot:

1. **Go to Copilot Studio.**
2. **Click on the copilot** you want to share.
3. Click on **three dots (:)** → **"Share"**.
4. Select a **user, security group, or email address**.
5. Assign the appropriate **role** (Author, Contributor, Manager, etc.).

Authentication and Sharing Interdependence:

- **Authentication settings affect who can access copilots.**
- Options include:
 - **No authentication** – Anyone can access it.
 - **Authenticate with Microsoft (Entra ID/Teams/Power Apps)** – Users must log in.
 - **Manual authentication** – Requires explicit approval.

Organization-wide Sharing:

- You can **enable/disable** copilot access for **everyone in the organization**.
- If **Power Automate is used**, users need **explicit access to Power Automate flows**.

Security Group Sharing:

- **Security groups** in Microsoft 365 can be assigned permissions.
- **Users inherit permissions** from security groups.
- Users **must still be granted Power Automate permissions** separately.

Key Takeaways:

- **Security roles define access** (Author, Contributor, Manager, Viewer).
- **Authentication settings impact sharing behavior**.
- **Power Automate and Dataverse permissions must be considered**.
- **Security groups simplify large-scale permission management**.
